

The History and Philosophy of CBIS

Vance Gudmundsen, CPCU, CLU
Vice President Government Affairs, Data Privacy,
Regulatory Compliance
FICO

Risk at Lloyd's of London - 1688

- Insurance began at Lloyd's coffee house in 1688, which was a popular place for sailors, merchants, and ship owners, and Lloyd provided reliable shipping news.
- Syndicates made bets on safe passage.
Risk of loss was determined by:
 - condition of the ship
 - ship's route
 - type of cargo (perishable; cost)
 - weather reports
 - captain's experience and reputation
- Examples of a person's past discipline and responsibility have always been predictive of current risk of loss.

CBIS is not intuitive

Q: What is the connection between a person's credit profile and her likelihood of having an insurance loss?

A: The American Academy of Actuaries' says the test of a valid risk classification characteristic is whether there is a "reasonable relationship" between the characteristic and the hazard insured against:

[I]n insurance it is often impossible to prove statistically any postulated cause and effect relationship. Causality cannot, therefore, be made a requirement for risk classification systems.

Often causality is not used in its rigorous sense of cause and effect but in a general sense, implying the existence of a plausible relationship between the characteristics of a class and the hazard insured against. Living in a river valley would not seem to cause a flood insurance claim, but it does bear a reasonable relationship to the hazard insured against and thus would be a reasonable basis for classification.

Risk classification characteristics should be neither obscure nor irrelevant to the insurance provided, but they need not always exhibit a cause and effect relationship.

Rating is quantifying risk

- Each applicant presents a risk of loss. Rating is a technique to quantify the risk of loss.
The higher the risk, the higher the premium.
- Rating and underwriting depend on the risk.
- Where risk is unknown, rate builds in a risk premium.
Example: Basel III and Dodd-Frank require capital retention (i.e., cushion) based on the size and riskiness of a creditor's loans and investments

Risk premium

- When an insurer has more confidence in the rates, there is less need to build in a risk premium
- Better risk selection means
 - (i) an insurer is more willing to underwrite more applicants
 - (ii) with rates that are lower
- CBIS is not a redistribution of insurance premiums: it is a reduction of the risk premium

Rating must find the right balance

- Average of all losses ÷
of participants
- Every person presents a
unique risk profile
- adverse selection
- not predictable

Under the pure average approach, the pot is right, but everyone's risk is incorrect
 Example: 100 people; 10 losses; \$5000 per loss; \$50,000 total loss costs
 Result = each person pays \$500

The law of large numbers does not work under the unique risk profile approach

Balance: rating factors such as driving record; vehicle type; age, gender; geo-
 location; credit based characteristics

Adverse selection = the great equalizer

In a competitive marketplace, with an elastic (price sensitive) demand curve, insurers cannot deviate from the best rating methodology:

- If insurer does not choose the best method of matching rate with risk, the good risks will go elsewhere (lower premiums) and the bad risks

Rating factors: the science and the art

- Before statistics, rating and underwriting was done by raters' instincts and biases
- With statistics, insurance is based on a large number of similar exposure units:
"exposure units" = rating factors (the science)

"similar" = actuarial discretion (the art)

Rating factors:

Risk splitters

- Actuaries would use any factor if:
 - a risk splitter (e.g., vehicle color)
 - easily and reliably collected; (e.g., credit profile)
 - not a proxy or double counted (e.g., income and home value)
 - not unfair (e.g., mileage), easily manipulated (e.g., favorite color), or illegal (e.g., genetics)
- Next great risk splitters?
 - usage based insurance
 - birth order

Scoring models are rating tools

- Models assign λ to risk factors; group exposure units together – what risk is being quantified?
- FICO's multivariate algorithms produce Credit risk model (odds-to-score ratio)

Rank order is consistent over time
Odds-to-score ratio can fluctuate
(angle of line can change)

CBIS model (loss ratio relativity-to-score ratio)

- The score (model's output) rank orders risk so that rating decisions can be made.

Regulators enforce rating laws

- There are social reasons why certain rating factors should be disallowed in the rating process – even if predictive
- Regulators will prohibit rates if they are inadequate, excessive, or unfairly discriminatory:

Standards

inadequate

excessive

unfairly discriminatory

Regulatory Concerns

financial security of insurer

consumer protection

legal or societal

Discrimination is actuarial unfair discrimination is illegal

- Choosing rating factors and similar exposure units involves discrimination
- There are three types of unfair discrimination:
 - based on prohibited factors (unfair or deceptive acts and practices statutes and regulations)
 - based on proxy factors (e.g., wearing hijab; / subscription)
 - disparate impact (race-neutral rating factors, where intent is not relevant)
- CBIS does not discriminate on any of these bases
